Neutralized diphthongization inventory in Chongqing Mandarin

Hailang Jiang, University College London

Summary. This study models the process of diphthongization of 5 high vowels in Chongqing Mandarin (CM) using dispersion theory under a scalar vowel system. The main takeaways are that diphthongization takes place only when phonotactics requires a marked structure *[+hi][+hi] to be repaired, and the diphthongs neutralize because lowered high vowels have a more narrow scale for F2 which does not accommodate contrastive qualities of front/back vowels, respectively.

Data. All discriptive data are collected and transcribed by me who is a native speaker of CM. In CM, in utterance-final positions, 5 high vowels diphthongize with 3 qualities, i.e., [i, y, u, u, \downarrow^1] \rightarrow [ii, yi, uo, uo, ie] / __#. The examples in (1) illustrate the alternations of the five vowels (in red).

Non-high monophthongs ([pe:³¹] 'white', [kho:²¹³] 'class', [pa:³¹] 'eight'), a vowel in a closed syllable ([sin³⁵] 'heart') and the second part of an underlying diphthong ([pai²¹³] 'failure'), do not diphthongize utterance-finally.

Motivation of diphthongization. I analyzes diphthongization as fission. Note that non-high vowels are lengthened utterance-finally (e.g., /pe³¹/[pe:³¹] 'white'), I argue that high vowels are lengthened as well, making all utterance-final syllables bimoraic. I do not distinguish between a long vowel [i:] and vowel geminate [ii] here because such a structure does not occur elsewhere in CM. However, utterance-final plain long high vowels like [ii]# are not tolerated here due to a general OCP constraint banning *[+high][+high] sequences in the domain of a syllable (following Gong & Zhang 2021), making 'long' or geminate vowels like *[ii] illicit. Evidence is that CM disallows rhymes like *ju, *qi, *wi, etc., e.g., 'New York' is borrowed as [ljəu.jo], not *[lju.jo]. Thus, the qualities of the 'offglides' of the diphthongized vowels are lowered to a minimal degree. That means, they resemble the corresponding original part (e.g., [i] vs [i]), but surprisingly they end up with 3 qualities only, with some neutralized.

Failure of a featural vowel system. The difficulties to model this under the featural vowel system are: (1) No more room for additional distinguished height level. The three monophthongs [i, e, a] already occupy all possible levels under a system with two binary features of height, [high] and [low]; adding [i] into it has to be companied by additional features like [tense], but this is irrelevant to the crucial contraint banning [+high] / [+high] __ at effect here. (2) No phonetic motivation for neutralization. To account for it, we can only specify [i] by deleting a feature of [round] from [i, y] after being lowered, but it is not clear why we do not keep two unique offglides [i] and [y].

See Table 1 for a tentative messy featural vowel system for all front vowels, where there are 3 levels of height but with [tense], and [tense] and [round] alternate between an unspecified value [0] and a specified value [+]/[-], with no articulatory and perceptual ground at all. Thus a finer-grained scalar system, which can accommodate phonetic mechanism is required.

¹ This [\mathfrak{z}] is called an 'apical vowel'. It is an allophone of /i/ which occurs after onsets $\{\widehat{ts}, \widehat{ts}^h, s, z\}$, as a nucleus of the syllable. Given its allophonic status and the fact that it behaves together with the other four dorsal high vowels, it should be considered as a high vowel phonologically.

i [-rd][0tense], y [+rd][0tense]	[+hi][-lo]	6	5	4	3	2	1	F2/F1
I [0rd][-tense]	r 1.:3r 1.3	i	y			ш	u	1
e [+tense]	[-hi][-lo]	Į l	ı y y			$\mathbf{U}^2\mathbf{U}$	υ υ	2
a	[-hi][+lo]	/ /	/ e	Э	ş	0	/ /	3

Table 1. A featural vowel system.

Table 2. A scalar vowel system.

Scalar modeling with Dispersion Theory. A scalar system is demonstrated in Table 2. The apical vowel [1] is ignored for time being. There are at least 6 units in the dimension of F2 from 1 to 6. For dimension of F1, only the smallest 3 units suffice for current purposes. The essential phonetic property of this scalar system is that, for F1 = 2, the two peripheral units (2, 1) and (2, 6) are disallowed due to the articulatory property of the oral cavity, i.e., the articulatory space is shaped like a triangle (e.g., Ladefoged 2006, Odijk & Gillis 2022, among many others), indicated by shaded area in the right table. It can be formalized into an *Effort constraint using Flemming's (2004) terms. The consequence of the narrowing of F2 scale from F1 = 1 to F1 = 2 is that the minimal vertical lowering of [i] has to be accompanied by a horizonal shift inward, to satisfy *Effort, resulting in [1] (2, 5.5). However, the minimal vertical lowering of [y] does not require an inward shift, resulting in [y] (2,5); otherwise, a shifted [y] (2, 4.5) violates a faithfulness constraint on horizontal position. The consequence of these two lowering is that [1] and [y] are too close in the dimension of F2 and cannot be perceptually contrastive, violating Flemming's (2004) MINDIST (F2) = 1. Therefore, only one of [1] and [y] can be retained. Similarly, we have to drop of of the back vowels [v] and [v]. Following Flemming (2004), given the number of contrast pair (1 here), contrast has to be as salient as possible, so [1] and [v] at both endpoints of the F2 scale (given F1 = 2) are reserved. Thus, the neutralization process is explained with widely established phonetic motivation. A tableau is given to demonstrate the rankings of relevant constraints.

A tableau for predicting vowel inventory at F1 = 2, as a result of high vowels' partial lowering

									0
6-5-2-1	i-y-ш-u ³	*EF	M=1	M=2	M=3	M=4	M=5	MC	HF
5.5-1.5	ı I-Ω		i i i i				*	$\sqrt{}$	****
5.5-5-2-1.5	I-ἦ-Ū-Ω		*!*	**	**	****	*****	777777	**
5.5-4.5-2.5-1.5	I <mark>-Y-U</mark> -℧			*!*	**	****	*****	777777	****
6-5-2-1	Ĭ-I-Ω-Ω	*!*		**	**	***	****	777777	
5-2	Y- U					*!	*	$\sqrt{}$	**

*EF = *EFFORT, M = MINDIST(F2), MC = MAXIMIZECONTRAST (note this is a positive constraint; the more $\sqrt{\ }$, the more harmonic the candidate is), HF = HORIZONTALFAITHFULNESS.

The mystery of the apical vowel. $[\!\!1\!] \rightarrow [\!\!1\!\!] = [\!\!1\!\!] / _\#$. This is a very tricky case, as an apical vowel fissions with an additional dorsal vowel. Conventional acoustic formant analysis for dorsal vowels does not apply. Here is a tentative analysis: $[\!\!1\!]$ is phonologically high given its allophonic status of /i/, so it lengthens and then diphthongizes; $[\!\!1\!]$ forms a constriction near the alveolar ridge at the fronter area of the oral cavity (Lee-Kim 2014), so articulatorily the closest to it is a front vowel, probably $[\![\epsilon]\!]$, but further measurement is required. I leave this issue open to future research. At least the analysis in the previous section at the level of $[\![\epsilon]\!]$ is even lower than that of $[\![\epsilon]\!]$ (F1 = 3).

² For the sake of brevity, I use the ad hoc notation [v] = [v] in stardard IPA here, which can be considered as an unrounded version of [v]. The two form a pair, as [I] and [Y].

³ It actually means the correspondents of [i-y-u-u] when they are (partially) lowered to the level of F1 = 2.
